Projecting emissions to determine plan impact

In order to determine whether the Climate Action Plan could result in community wide emissions levels that meet the City Council-adopted targets in 2015 and 2025, projections of greenhouse gas emissions were developed for two scenarios:

- 1. Baseline emissions scenario.** This is a “status quo” scenario that includes activities that will influence community emissions regardless of whether Climate Action strategies are undertaken. This includes assumptions about the growth in energy use due to population and job growth in the city, assumptions about Xcel Energy’s fuel mix and new CAFE standards for vehicles.
- 2. Plan scenario.** This is the Climate Action scenario, in which Minneapolis is able to meet all the goals established in the plan. Meeting these goals would change the growth in energy use, the expansion of renewables, emissions from transportation and the amount of waste disposal.

Both baseline and plan scenarios were developed for all the major greenhouse gas sources in the buildings, transportation and waste categories. These were then combined to develop a cumulative baseline and plan scenario.

Figure XX shows the contribution of each category of strategies to the overall emissions reduction potential of the plan. In the baseline scenario, Minneapolis would be responsible for 4.9 million metric tons (mmt) of CO₂e in 2025, a 24% reduction from 2006, but still short of the City’s adopted target of 4.16 mmt. By meeting the plan goals, Minneapolis would be responsible for 3.9 mmt in 2025, or nearly 5% below the adopted target.

Baseline emissions scenario

The “status quo” baseline incorporates a number of assumptions about future changes to our energy, transportation and waste systems that will likely take place regardless of any climate action strategies advanced in Minneapolis.

Under the baseline scenario, community greenhouse gas emissions are expected to fall 4 percent between 2010 and 2025 and 17 percent from 2006 to 2025. This trend is most heavily affected by slowly growing electricity usage, cleaner fuels for making electricity, and more fuel-efficient on-road

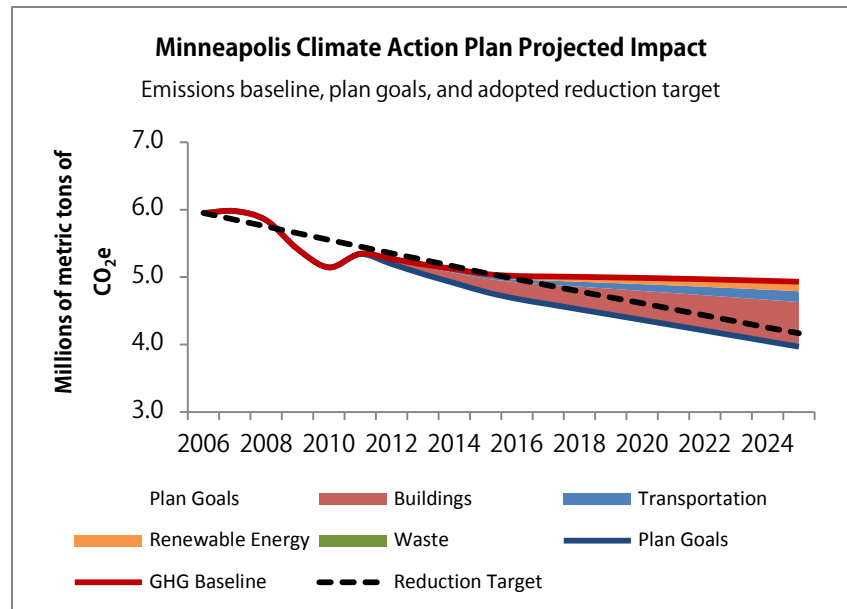

Figure 1. Climate Action Plan Projected Impact

transportation as vehicles are replaced. Figure 2 shows a summary of the baseline greenhouse gas emissions scenario.

Electricity & natural gas baselines

The baseline greenhouse gas emissions scenario assumes Xcel Energy will continue to provide electricity to Minneapolis with a greenhouse gas intensity consistent with their 2011 Integrated Resource Plan (IRP) filed with the State Public Utilities Commission. These

plans show a reduction in the greenhouse gas intensity of electricity between 2010 and 2025, with most of these reductions happening between 2010 and 2015. Table 1 shows the greenhouse gas intensity from Xcel Energy through 2025. Xcel provided estimates to the City of Minneapolis of intensity figures for the years 2015 and 2025. For each year up to and including the 2011 calendar year, the City has received verified greenhouse gas intensity figures from Xcel. Years between 2011 and 2015 and between 2015 and 2025 were estimated based on a straight line trend.

Based on discussions at the Buildings & Energy Working Group, which included an Xcel Energy representative, an annual rate of growth in electricity consumption was developed for the baseline scenario – 0.5%. This growth rate was in recognition of the planned growth in households and jobs in Minneapolis through 2025. Total electricity consumption in Minneapolis has declined over 2% between 2006 and 2011. The Energy Information Agency (EIA) predicts in their 2013 Annual Energy Outlook that electricity consumption in MRO West, our electricity grid region which includes multiple states, will grow between 0.4% to 1.4% annually between 2010 and 2025.¹

Local combustion of natural gas (in residential and commercial heating, and industrial applications) will produce 0.0053060156 MT CO₂e per therm. No changes in combustion efficiency were assumed in either the baseline or goals scenario. The Buildings & Energy Working Group, which included a Centerpoint Energy representative, developed a zero percent annual growth rate in natural gas consumption for the baseline scenario. The EIA predicts that the residential use of natural gas in the West North Central Region, which includes Minnesota and six other Midwestern states, will decline almost every year between 2010 and 2025, with the annual decline slowing to -0.5% by 2025.¹ According to the EIA, commercial consumption of natural gas is expected to decline slowly on an annual basis through 2025.

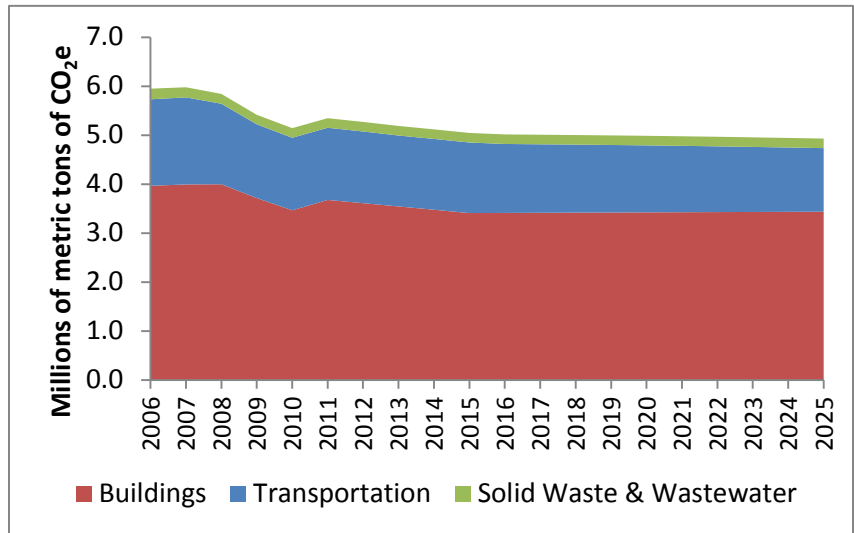

Figure 2. Minneapolis Greenhouse Gas Emissions Summary - Baseline Scenario

¹ http://www.eia.gov/forecasts/aeo/er/tables_ref.cfm

Consistent with the approach in the Minneapolis Greenhouse Gas Inventory², electricity produced at HERC and sold to Xcel Energy was subtracted from the total electricity emissions in each year to avoid double-counting.

Table 2 shows the greenhouse gas emissions from electricity and natural gas consumption under the baseline scenario.

University of Minnesota steam plant baseline

The steam plant on the University of Minnesota's Minneapolis campus provides heat to the campus through a district energy system. The plant is a source of greenhouse gas emissions in Minneapolis, and is fueled by coal, natural gas, fuel oil and oat hulls. Under the baseline scenario, the steam plant was assumed to continue operating with its current fuel mixture through 2025. This would produce greenhouse gases similar to 2010 levels, of roughly 127,000 metric tons per year.

Transportation baseline

The key drivers of change in transportation-related emissions are road transportation and the Minneapolis-Saint Paul International airport. Rail and barge traffic in the city make up a small portion of emissions. Within the road transportation area, which is the largest source of transportation-related emissions, vehicle fuel efficiency and the number of vehicle miles traveled (VMT) have significant impacts on emissions levels. The full methodology for the inventory of transportation-related greenhouse gases can be found in the Minneapolis Greenhouse Gas Inventory².

Road transportation baseline

The Metropolitan Council maintains a regional traffic and transportation model for the purposes of effectively planning the region's transportation system. Based on the assumptions contained in that model, VMT in Minneapolis is projected to grow at a rate of 0.3% for the entire period of 2010 to 2030. This annual growth rate was used in the baseline emissions calculation for road transportation.

The on-road vehicle fuel efficiency standards enacted in 2012 by the US Environmental Protection Agency were included in the baseline emissions scenario for transportation. While these would require new cars in some categories to achieve 54.5 miles per gallon in 2025, many older vehicles would still be on the road at that time. The US Energy Information Agency developed a set of average car and truck miles per gallon estimates that included the new CAFE rules as part of their 2012 early release of the Annual Energy Outlook. Table 4 shows the fuel economy assumptions used in the baseline emissions scenario, which are consistent with the 2012 EIA AEO.

Both the baseline emissions scenario and the plan scenario assume the fleet distribution of cars, light trucks and heavy duty vehicles remains the same between 2010 and 2025.

The baseline emissions scenario also assumes that Minnesota's biodiesel and ethanol mandates remain the same from 2010 to 2025. This means that gasoline will continue to contain 10% ethanol through 2025. At the time the Climate Action Plan was being developed, Minnesota issued new rules for ethanol in gasoline, calling for a 20% requirement for gasoline starting in 2015. This means the baseline emissions scenario for road transportation will likely be higher than actual emissions after 2015. Diesel

² http://www.minneapolismn.gov/sustainability/reports/sustainability_carbon

fuel will contain 5% biodiesel until 2013, when the blend will increase to 10%. In 2016, the blend will increase to 20%³.

MSP Airport baseline

The Minneapolis-Saint Paul International airport (MSP) is a significant source of greenhouse gas emissions and is included in the Minneapolis Greenhouse Gas Inventory. Including airport-related emissions is somewhat unique among community inventories.

The baseline emissions scenario assumes that emissions from the airport will rebound from a low point in 2010 and grow at 1% per year from 2012 through 2025. Table 6 shows the baseline emissions from the airport and air travel.

Small sources baseline

Small sources in the Minneapolis Greenhouse Gas Inventory included rail and barge traffic and backup power supplies. Emissions from these sources were projected to continue at equal levels of 26,262 MT CO₂e in both the baseline and plan scenario.

Total transportation baseline

Table 7 shows the total greenhouse gas emissions from the transportation sector in the baseline scenario. While emissions from the airport and air travel are expected to increase 16% between 2010 and 2025, emissions from road transportation are projected to decline by 22%, due to improvements in vehicle fuel economy and the transition to cleaner fuel sources. Overall, by 2025 emissions in the transportation baseline are projected to decline 12% from 2010 and 27% from 2006.

Solid waste and wastewater treatment baseline

The baseline scenario for greenhouse gas emissions from solid waste disposal are based on assumptions of changes in the solid waste stream under the status quo. Under the baseline scenario, emissions from the processing of wastewater are assumed to remain flat through 2025.

Solid waste baseline

Greenhouse gas emissions from solid waste occur when solid waste disposed of by Minneapolis residents and business is processed in a landfill or energy recovery facility. In the baseline scenario, the total waste stream was anticipated to grow at 1.2 percent annually. This figure is based on the Hennepin County Solid Waste Master Plan assumptions.

In 2010, recycled material accounted for 32.5 percent of the total Minneapolis waste stream. This percentage was expected to grow to 40 percent of the waste stream by 2025 under the baseline scenario. Source-separated organics are expected to grow to 6 percent of the waste stream by 2025. Household Hazardous Waste (HHW), landfilled construction debris, and yard waste tonnages are expected to remain flat through 2025. Tonnage estimates for the baseline scenario are shown in Table 8.

In the community greenhouse gas inventory completed in 2012, greenhouse gas emissions from the burning of waste at the Hennepin Energy Recovery Center (HERC) were included in solid waste emissions estimates for 2006 – 2010. Because HERC operates under state permits limiting the amount of waste that can be processed, the baseline scenario assumes that the amount of waste from other communities processed at HERC would decline as Minneapolis waste sent to HERC increased. Total

³ <http://www.afdc.energy.gov/laws/laws/MN#Laws and Regulations>

greenhouse gas emissions from HERC are expected to stay flat at around 131,000 MT through 2025 in the baseline scenario.

Under the baseline scenario emissions from Minneapolis-generated solid waste would increase 3 percent between 2010 and 2025. Table 9 shows baseline scenario greenhouse gas emissions from solid waste and wastewater.

Plan emissions scenario

The Plan emissions scenario is the Climate Action scenario, in which Minneapolis is able to meet all the goals established in the plan. Meeting these goals would change the growth in energy use, the expansion of renewables, emissions from transportation and the amount of waste disposal.

Under the Plan emissions scenario, community greenhouse gas emissions are expected to fall 23 percent between 2010 and 2025 and 33 percent from 2006 to 2025. This trend is most heavily affected by

meeting the aggressive energy efficiency goals, cleaner fuels used for making electricity, and flat or declining vehicle miles traveled combined with more fuel-efficient on-road transportation. Figure 3 shows a summary of estimated emissions through 2025 under the plan scenario.

Figure 3. Minneapolis Greenhouse Gas Emissions Summary - Plan emissions scenario

Electricity & natural gas plan scenario

The plan greenhouse gas emissions scenario, like the baseline scenario, assumes Xcel Energy will continue to provide electricity to Minneapolis with a greenhouse gas intensity consistent with their 2011 Integrated Resource Plan (IRP) filed with the State Public Utilities Commission. These plans show a reduction in the greenhouse gas intensity of electricity between 2010 and 2025, with most of these reductions happening between 2010 and 2015. Table 1 shows the greenhouse gas intensity from Xcel Energy through 2025. Xcel provided estimates to the City of Minneapolis of intensity figures for the years 2015 and 2025. For each year up to and including the 2011 calendar year, the City has received verified greenhouse gas intensity figures from Xcel. Years between 2011 and 2015 and between 2015 and 2025 were estimated based on a straight line trend.

Electricity usage

Based on discussions at the Buildings & Energy Working Group, which included an Xcel Energy representative, an annual rate of growth in electricity consumption was developed for the baseline scenario – 0.5%. The Buildings & Energy Working Group adopted energy efficiency goals – 20% efficiency over the baseline in commercial/industrial buildings by 2025 and 15% efficiency over the baseline in residential buildings. Using baseline estimates for electricity usage, these goals were used to estimate 2025 electricity usage under the plan scenario.

Under the plan scenario, electricity use in commercial and industrial buildings in 2025 would be down 15 percent from 2011 levels, and residential use would be down 8 percent.

Consistent with the approach in the Minneapolis Greenhouse Gas Inventory⁴, electricity produced at HERC and sold to Xcel Energy was subtracted from the total electricity emissions in each year to avoid double-counting.

Renewable energy

The plan scenario includes aggressive targets for renewable energy use by Minneapolis customers. This could include local, distributed generation or directly purchased renewable energy, like the Wind Source program currently run by Xcel Energy. Renewable energy was assumed to contribute to electrical usage only.

Under the plan scenario, 10% of electricity consumption by commercial and residential customers comes from renewable, carbon-free sources. This would mean an increase to 360 GWhs in 2025 from current levels of 55 GWhs in 2011. Total electricity consumption in 2025, from which the 10% renewable productive figure was calculated, was based on the estimates after achieving energy efficiency gains (see above).

While it is unlikely that renewable projects and participation in programs would occur in a linear fashion, for the purposes of these estimates, a straight-line trend was used to estimate level of renewable energy in the years between 2011 and 2025.

Natural gas usage

Local combustion of natural gas (in residential and commercial heating, and industrial applications) will produce 0.0053060156 MT CO₂e per therm. No changes in combustion efficiency were assumed in either the baseline or goals scenario. The Buildings & Energy Working Group, which included a Centerpoint Energy representative, developed a zero percent annual growth rate in natural gas consumption for the baseline scenario. Similar to the approach used for electricity, the energy efficiency goals adopted by the Working Group were used to estimate natural gas usage under the plan scenario starting with the baseline estimates.

Under the plan scenario, natural gas usage in commercial buildings in 2025 would be down 20 percent from 2011 levels, and residential use would be down 15 percent. A goal for reduction of usage in industrial buildings was not adopted by the Working Group.

Table 10 shows greenhouse gas emissions from electricity and natural gas under the Plan scenario.

⁴ http://www.minneapolismn.gov/sustainability/reports/sustainability_carbon

University of Minnesota steam plant plan scenario

The steam plant on the University of Minnesota's Minneapolis campus provides heat to the campus through a district energy system. The plant is a source of greenhouse gas emissions in Minneapolis, and is fueled by coal, natural gas, fuel oil and oat hulls. Under the plan scenario, greenhouse gas emissions from the steam plant were assumed to decline to 60,000 MT annually by 2025. According to the Climate Action Plan for the University of Minnesota Twin Cities, the University plans to reduce coal use at the steam plant by 85% by 2016. This would reduce emissions by 27,300 metric tons⁵. By 2021, the University plans to have a Combined Heat and Power generating plant operational which will augment the University's Southeast steam plant, reducing emissions by another 65,000 metric tons annually. These changes may bring the emissions from the steam plant below 60,000 metric tons by 2025.

Transportation plan scenario

The key drivers of change in transportation-related emissions are road transportation and the Minneapolis-Saint Paul International airport. Rail and barge traffic in the city make up a small portion of emissions. Within the road transportation area, which is the largest source of transportation-related emissions, vehicle fuel efficiency and the number of vehicle miles traveled (VMT) have significant impacts on emissions levels. The full methodology for the inventory of transportation-related greenhouse gases can be found in the Minneapolis Greenhouse Gas Inventory².

Road transportation plan scenario

The Transportation and Land Use Working Group developed a zero percent annual growth rate in VMT as the goal for the Climate Action Plan.

The on-road vehicle fuel efficiency standards enacted in 2012 by the US Environmental Protection Agency were used to calculate the baseline and plan emissions scenario for transportation. While these would require new cars in some categories to achieve 54.5 miles per gallon in 2025, many older vehicles would still be on the road at that time. The US Energy Information Agency developed a set of average car and truck miles per gallon estimates that included the new CAFE rules as part of their 2012 early release of the Annual Energy Outlook. Table 4 shows the fuel economy assumptions used in the baseline emissions and plan scenario, which are consistent with the 2012 EIA AEO.

Both the baseline emissions scenario and the plan scenario assume the fleet distribution of cars, light trucks and heavy duty vehicles remains the same between 2010 and 2025.

The baseline emissions scenario also assumes that Minnesota's biodiesel and ethanol mandates remain the same from 2010 to 2025. The plan scenario, including the strategy of supporting a state mandate for low-carbon fuels, assumed that a 20% requirement for ethanol or other form of low carbon fuel would be enacted and be in force by 2025. After 2015, the low carbon standard was estimated to take effect along a linear trend line from 10% to 20% in 2025.

At the time the Climate Action Plan was being developed, Minnesota issued new rules for ethanol in gasoline, calling for a 20% requirement for gasoline starting in 2015. This means the baseline emissions scenario for road transportation will likely be higher than actual emissions after 2015, and the plan

⁵ Climate Action Plan for the University of Minnesota, Twin Cities. December, 2011. http://rs.acupcc.org/site_media/uploads/cap/812-cap_5.pdf

scenario likely more accurate. Diesel fuel will contain 5% biodiesel until 2013, when the blend will increase to 10%. In 2016, the blend will increase to 20%⁶.

MSP Airport plan scenario

The Minneapolis-Saint Paul International airport (MSP) is a significant source of greenhouse gas emissions and is included in the Minneapolis Greenhouse Gas Inventory. Including airport-related emissions is somewhat unique among community inventories.

The plan emissions scenario assumes that emissions from the airport will remain flat at 2010 levels through 2025. The Greenhouse Gas Report⁷, developed for the Metropolitan Airports Commission in 2010, suggests that the airport position itself to meet or exceed any reduction goals, and continue to track its own emissions. The report identifies a number of strategies the MAC can continue to undertake to reduce its impacts. Air travel and related emissions are highly dependent on the economy, so future changes in emissions at the airport will need to be monitored closely.

Small sources baseline

Small sources in the Minneapolis Greenhouse Gas Inventory included rail and barge traffic and backup power supplies. Emissions from these sources were projected to continue at equal levels of 26,262 MT CO₂e in both the baseline and plan scenario.

Total transportation baseline

Table 11 shows the total greenhouse gas emissions from the transportation sector in the plan scenario. Emissions from road transportation are projected to decline by 31% from 2010 levels, due to flat VMT growth, improvements in vehicle fuel economy and the transition to cleaner fuel sources. Overall, by 2025 emissions in the transportation baseline are projected to decline 23% from 2010 and 36% from 2006.

Solid waste and wastewater treatment plan scenario

The plan scenario for greenhouse gas emissions from solid waste disposal are based on assumptions of changes in the solid waste stream under strategies developed in the Waste & Recycling Working Group. Under the baseline scenario, emissions from the processing of wastewater are assumed to decrease by 8 percent from 2010 levels by 2025.

Solid waste baseline

Greenhouse gas emissions from solid waste occur when solid waste disposed of by Minneapolis residents and business is processed in a landfill or energy recovery facility. In the plan scenario, the total waste stream was anticipated to have flat growth as strategies are implemented.

In 2010, recycled material accounted for 32.5 percent of the total Minneapolis waste stream. This percentage is expected to grow to 50 percent of the waste stream by 2025 under the plan scenario. Source-separated organics are expected to grow to 15 percent of the waste stream by 2025. These goals are consistent with Hennepin County's adopted Solid Waste Master Plan, and in the case of organics collection, exceed it.⁸

⁶ <http://www.afdc.energy.gov/laws/laws/MN#Laws and Regulations>

⁷ Greenhouse Gas Report. December, 2010. Metropolitan Airports Commission. <http://www.mspairport.com/docs/about-mpsp/sustainability/MSP-2010-GHG-Report-Jan-2011.aspx>

⁸ <http://www.hennepin.us/solidwasteplanning>

Household Hazardous Waste (HHW), landfilled construction debris, and yard waste tonnages are expected to remain flat through 2025. Tonnage estimates for the plan scenario are shown in Table 12.

In the community greenhouse gas inventory completed in 2012, greenhouse gas emissions from the burning of waste at the Hennepin Energy Recovery Center (HERC) were included in solid waste emissions estimates for 2006 – 2010. Because HERC operates under state permits limiting the amount of waste that can be processed, the plan scenario assumes that the amount of waste from other communities processed at HERC will increase as Minneapolis waste sent to HERC decreases. Total greenhouse gas emissions from HERC are expected to stay flat at around 131,000 MT through 2025 in the plan scenario.

Under the plan scenario emissions from Minneapolis-generated solid waste would decrease by 51% percent between 2010 and 2025.

Wastewater treatment

The Metropolitan Council, which operates the wastewater treatment facility that serves Minneapolis, has aggressive energy goals. By 2015, the Council aims to reduce purchased energy use by 25% from 2006 levels while meeting or exceeding current levels of service⁹. They will meet this goal through energy efficiency practices and deploying renewable energy for internal energy use.

The plan scenario assumes that through a combination of Met Council's improvements and a reduction in the proportion of wastewater treated at the plant that is coming from Minneapolis, greenhouse gas emissions from wastewater treatment will be 25% below 2006 levels in 2025. Reductions in wastewater flow are addressed primarily in the Buildings & Energy strategies including home energy efficiency visits which include water use reduction efforts.

Table 13 shows plan scenario greenhouse gas emissions from solid waste and wastewater.
